Nickel (Ni) contamination of the environment from industrial sources has been reported to affect living organisms and is being considered as a global concern (Khodadoust et al., 2004; Cecchie and Zanchi, 2005). Irrigation of agricultural fields with Ni containing wastewater is affecting crop yield and also creating potential risk of biomagnification by entering into the food chain (Sanders et al., 1987; Singh et al., 2012).

Different mechanisms of Ni resistance have earlier been documented (Gadd, 1988; Nies, 1999; Sar et al., 2001; Salvador et al., 2007; Desale et al., 2014), of which certain mechanisms could be exploited for successful remediation of sites contaminated with such hazardous metal. Screening of Ni resistant microbes from contaminated sites with potential Ni immobilizing ability could provide a significant impact on environmental management. Moreover, such bacterial inoculants having metal immobilizing ability with plant growth promoting (PGP) features have opened other eco-friendly measures for sustainable agriculture (Burd et al., 2000; Faisal and Hasnain, 2006; Denton, 2007; Rajkumar and Freitas, 2008). Considering this background, the objectives of this study were to isolate and characterize a Ni resistant bacterial candidate from Ni contaminated soil and to examine its remediating ability with PGP features under experimental conditions.

Ni resistant bacterial strain was isolated from industrial waste contaminated soil (pH 7.4, Ni content – 2.9 mg/Kg of soil) near Durgapur, West Bengal, India. Dilution plate technique was followed to isolate the Ni resistant strain. The bacterial strain that showed maximum tolerance to Ni (as NiCl$_2$, 6H$_2$O) on nutrient agar (NA) medium (HiMedia, India) was selected and designated KUNi5. The colony was further transferred to modified Tris minimal agar (TMA) medium (Sar et al., 1998) for culture purification and was maintained. The maximum tolerance levels of KUNi5 to other heavy metals were also assessed in modified Tris minimal broth (TMB).

The isolate KUNi5 was identified on the basis of its morphological and biochemical features (Vos et al., 2009) and 16S rDNA sequence analysis. The base sequence was aligned using BLAST function (Altschul et al., 1990) at the National Center for Biotechnology Information (NCBI) database for its identification.

To determine the effect of Ni on bacterial growth under aerobic culture conditions, equal volume of young cell suspensions were inoculated (~4 log CFU/mL) into modified TMB with different concentrations of Ni (0.5, 1.0, 2.0, 3.0 and 4.0 mM) as NiCl$_2$, 6H$_2$O separately and each set including the control set was incubated at 37°C on a rotary shaker. The growth of KUNi5 was measured by colony count method at certain time intervals on modified TMA plates. Ni removal by KUNi5 at each treatment regime was also determined by quantifying the residual amount of Ni present in the medium. Supernatant was harvested by centrifugation and was acid-digested; Ni contents in the supernatants were measured by Atomic Absorption Spectrophotometer.
(jICE 3000 AAS, Thermo Scientific, Austria). An uninoculated set for each treatment regime was also maintained and processed similarly to monitor the artifacts that might arise owing to metal chelation on the surface of the container. The percentage of Ni removal was calculated following the equation: R (%) = \((C_i - C_f) \times 100/C_i\) \(C_i = \) Initial Ni concentration; \(C_f = \) Equilibrium Ni concentration.

To study the effect of initial pH on Ni removal under culture conditions, modified TMB supplemented with 2 mM Ni with pH values ranging from 5 to 8 was inoculated with equal volume of bacterial inoculum and incubated at 37°C. The growth patterns of KUNi5 and Ni removal at respective treatment regimes were also measured. The effect of temperature on Ni removal and growth under aerobic growth conditions was determined in TMB (pH 7) having 2 mM of Ni at different temperatures (30°C, 37°C, and 40°C).

The effects of other heavy metals separately (0.1 mM Cu as CuSO\(_4\)·5H\(_2\)O or 0.1 mM Co as CoCl\(_2\)·6H\(_2\)O or 0.1 mM Zn as ZnCl\(_2\), 0.1 mM Cd as CdCl\(_2\)·5H\(_2\)O) on Ni removal were studied. Equal volume of cell suspension was inoculated in modified TMB (pH 7, 2 mM Ni) to each treatment regime and incubated for 48 h at 37°C. Culture set without having any selected heavy metals other than Ni was considered as control. After 48 h the amount of Ni removal was measured as mentioned earlier.

Amount of Ni in different cell fractions were measured by growing the cells in modified TMB supplemented with 2 mM Ni for 48 h at 37°C. Cellular fractions were harvested and prepared following Sar et al. (2001). The amount of Ni in different fractions was measured after acid digestion as mentioned before. Fourier transform infra red (FTIR) spectroscopy was performed to visualize the shifts in the absorption spectrum of the treated cell fractions in comparison to the control one. Cells from both control (Ni free) and treated (2 mM Ni) sets were harvested after 48 h of growth and washed with HEPES-NaOH buffer (100 mM, pH 7.2), and were then lyophilized. Infra red spectra were obtained by using Spectrum One FT-IR Spectrometer (Perkin Elmer, USA).

For determining possible PGP features of KUNi5, 1-aminocyclopropane-1-carboxylate (ACC) deaminase, indole-acetic acid (IAA) and siderophore producing abilities were considered. ACC-deaminase activity of KUNi5 was qualitatively assayed following Dworken and Foster (1958). Siderophore and IAA production by KUNi5 were qualitatively determined following respective standard methods (Schwyn and Neillands, 1987; Sosa-Morales et al., 1997).

KUNi5 cells were found to be Gram-negative and rod shaped. Based on the analysis of 16S rDNA sequence (NCBI GenBank Accession No. KM277458), KUNi5 has been identified as a strain of Enterobacter asburiae. It could tolerate 15 mM Ni in nutrient broth and 10 mM Ni in modified TMB. The difference in tolerance limit in two different media might be due to the complexation of Ni with undefined ingredients in the nutrient broth thus lowered toxicity (Sau et al., 2008). KUNi5 showed varied degree of tolerance to heavy metals in the order of Ni>Zn>Cu>Co>Cd (10, 7, 5, 2 and 1 mM respectively) in TMB. Tolerance to different toxic metals might be due to the selection pressure of contaminant metals at the sampling site posed on the KUNi5 population. The strain showed ability to produce ACC deaminase, IAA and siderophore, which might be of important agronomic value for using as PGP candidate. PGP features of E. asburiae and its suitability of using in sustainable agriculture were also documented earlier (Ahemad and Khan, 2010; Zhao et al., 2011).

Growth retardation and extended lag phase of KUNi5 were found with increasing Ni concentration in the medium (Fig. 1a). Irrespective to the Ni concentration, highest cell mass was obtained after 48 h of growth. The extended lag phase might be due to the requirement of time for buffering the metal stress (Patel et al., 2006; Das et al., 2014). KUNi5 grew optimally better at pH 7 and 37°C under Ni stress (2 mM) conditions (Fig. 1b, c). Irrespective of the initial Ni concentration, pH of the medium and incubation temperature, highest Ni removal was found after 48 h and thereafter remained same (Fig. 1d, e, f). When initial Ni concentration was considered as the factor, maximum removal was found at an initial concentration ranging from 0.5 m to 2 mM of Ni in the medium. Incubation temperature of 37°C and pH 7 were found to be conducive for Ni removal. From the experimental analysis it seems that active biomass might play a crucial role on Ni removal. Other heavy metals were found to antagonize growth and Ni removal (Fig. 2). Cadmium was found to be most antagonistic than Co, Zn and Cu. Similar types of results were also observed with other bacteria (Fu and Maier, 1991; Hussein et al., 2004; Das et al., 2014). Decrease in Ni removal might be due to the growth inhibitory or competitive effect of other metals on Ni binding (Kaltwasser and Frings, 1980; Fu and Mier, 1991).

From the cellular fractionation study it was observed that most of the metals were accumulated (nmol of Ni/mg dry weight) in the membrane fractions (~53%) followed by periplasmic space (~34%) and cytosol (~13%). Such pattern of accumulation and sequestration of toxic cations was also reported earlier (Cha and Cooksey, 1991; Sar et al., 2001). In order to ascertain the role of different functional groups involved in Ni binding, FTIR analysis were done for both lyophilized control and treated (2 mM Ni) biomass. A large shift was found due to Ni exposure in the intensity of absorption band peak for OH stretch from 3300.61 cm\(^{-1}\) to 3446.68 cm\(^{-1}\) (Fig. 3). Small shifts occurred in the intensity of the bands 1539.03 cm\(^{-1}\) to 1546.21 cm\(^{-1}\)
Fig. 1. Growth response of KUNi5 in TMB with different concentration of Ni and without Ni as control (a), having 2 mM Ni at different pH (b), and having 2 mM Ni at different temperatures (c). Ni removal ability of KUNi5 grown in TMB at different time intervals with increasing Ni concentrations (d), at different pH values (e), and at different temperatures (f). Data are the mean of three replications with ± SE (p < 0.05).

Fig. 2. Growth response (a) and Ni removal ability (b) of KUNi5 grown in TMB having 2 mM Ni after 48 h in presence of other heavy metals (0.1 mM). Data are the mean of three replications with ± SE (p < 0.05).

Fig. 3. FTIR spectra of untreated (a) and 2 mM Ni treated (b) cell biomass of KUNi5. Major shifting in the intensity of absorption band peaks are indicated by [*].
indicating N-H bending and C-H stretching in amide II, and 1068.86 cm$^{-1}$ to 1063.29 cm$^{-1}$ suggesting asymmetric and symmetric stretching of PO$_2^-$ and P(OH)$_2$ or C-OH bonds in alcohols or polysaccharide of bacterial biomass (Jiang et al., 2004). It seems that positively charged metal ions bind to such negatively charged functional groups present on the bacterial cell fractions (Anand et al., 2006; Desale et al., 2014).

Thus, the strain KUN15 showed its promise for bioremediation of Ni-contaminated crop field and also as a plant growth promoting agent, although the extent of Ni immobilization and plant growth promotion under actual metal-polluted field conditions warrants further investigation.
