Submitted 27 November 2018, revised 17 January 2019, accepted 19 January 2019

Abstract

We observed the death of insect caterpillars of Spodoptera exigua in the laboratory culture line and identified Serratia marcescens as the bacterial causative agent of the insect death. We confirmed that S. marcescens had insecticidal activity against S. exigua and caused high mortality of larvae. The LC_{50} values of S. marcescens CFU per 1 cm^2 of insect diet surface were similar for all isolates. Our research reports novel strains with high pesticidal activity as candidates for future research on a new bioinsecticide. As bioinsecticides cannot be harmful to non-target organisms, we determined the pathogenic properties of S. marcescens to humans. We proved the ability of S. marcescens to damage mammalian epithelial cells. All strains had cytopathic effects to Vero cells with a cytotoxic index ranging from 51.2% ± 3.8% to 79.2% ± 4.1%. We found that all of the strains excreted catecholate siderophore – enterobactin. All isolates were resistant to sulfamethoxazole, tobramycin, gentamicin, ceftime, and aztreonam. We did not observe the ESBL phenotype and the integrons’ integrase genes. Resistance to sulfamethoxazole was due to the presence of the sulI or sul2 gene. The use of resistant S. marcescens strains that are pathogenic to humans in plant protection may cause infections difficult to cure and lead to the spread of resistance genes. The results of our study emphasize the necessity of determination of the safety to vertebrates of the bacteria that are proposed to serve as biocontrol agents. The novelty of our study lies in the demonstration of the indispensability of the bacteria verification towards the lack of hazardous properties to humans.

Key words: bioinsecticide, insecticidal activity, pathogenicity, pesticide safety, Serratia marcescens

Introduction

Due to the growing resistance of insects to synthetic pesticides, there is an urgent need for new biopreparations. Serratia marcescens is a species of Gram-negative rods (Hejazi and Falkiner 1997) that produces substances useful in different branches of industry and medicine (Siva et al. 2012). Some S. marcescens strains have been recognized as opportunistic or facultative pathogens of insects. They cause lethal septicaemia after penetration into the hemocoel. The first step of pathogenesis is the colonization of epithelial cells. After adhesion to the cells, the bacteria produce potential virulence factors, including extracellular toxins which are probably the most common factors of S. marcescens pathogenicity (Grimont and Grimont 2006). The pathogenicity of S. marcescens to insects makes these bacteria an interesting tool in the search of the new biological control preparation applied in plant protection. Liquid culture of S. marcescens had potential use as a biocontrol factor against insect pest of Lepidoptera Plutella xylostella (Jeong et al. 2010), Heliothis virescens (Sikorowski et al. 2001) and Helicoverpa armigera (Mohan et al. 2011). Additionally, S. marcescens could reduce the development of fungus and thus inhibit the appearance of some diseases of crops. The bacteria have an antagonistic effect towards plant pathogen belonging to oomycetes – Phytophthora parasitica – the causative agent of a disease known as gummosis (de Queiroz and de Melo 2006). It has been demonstrated that the whole S. marcescens cells (Sikorowski et al. 2001; Jeong et al. 2010; Mohan et al. 2011) as well as their isolated components (Khanafari et al. 2006; Patil et al. 2011; Aggarwal et al. 2015) had putative usefulness in biocontrol on condition that they are safe for non-target organisms.

As the whole bacterial cells could have a harmful effect on vertebrates, more desirable are the components produced by bacteria. The bioactive substances that may play an important role in plant protection produced by S. marcescens include several virulence agents:
prodigiosin (Patil et al. 2011) and chitinase (Mohan et al. 2011; Aggarwal et al. 2015) among them. Prodigiosin synthesized by \textit{S. marcescens} is active against insects of Coleoptera (Bidari et al. 2018) and Diptera. It has also medical utility due to antitumor, immunomodulating, antimycotic (Khanafari et al. 2006), and antibacterial features (Samrot et al. 2011). It induces apoptosis in some cancer cell lines, such as acute human T-cell leukemia hepatocellular cancer, breast cancer, and the TNF-stimulated cervix carcinoma (Khanafari et al. 2006). It can also be used as an inhibition agent of protozoan species (Grimont and Grimont 2006). Moreover, \textit{S. marcescens} synthesizes substances active against \textit{Pectobacteria} spp. that causes the soft rot disease of plant \textit{Amorphophallus konjac} (Wu et al. 2012). None of the previous studies on the usefulness of \textit{S. marcescens} in plant protection included the determination of pathogenic potential to humans of \textit{S. marcescens} strains and evaluation of their safety to vertebrates.

The same factors which make \textit{S. marcescens} the putative biological control organisms are these that in humans could facilitate bacterial cells adhesion, protect from host’s immune system and allow for tissue penetration. The pathogenicity factors include the fimbriae, the production of siderophores, the presence of cell wall antigens, the ability to resist to the bactericidal action of serum, the production of proteases and the cell-contact toxins that facilitate bacterial invasion, induce cytotoxicity and apoptosis of host cells (Franczek et al. 1986; Krzymińska et al. 2012).

Additionally, the antibiotic resistance of the strains should be considered due to the possibility of the spread of the genes conferring drug resistance. Antibiotic resistance genes are often incorporated into mobile structures such as plasmids, transposons, and integrons. The latter are genetic structures that capture and incorporate resistance gene cassettes and transform them into the functional genes (Cambray et al. 2010).

We have observed the death of beet armyworm \textit{Spodoptera exigua} Hübner (Lepidoptera: Noctuidae) larvae in the laboratory culture line of this insect pest. This encouraged us to isolate and identify the bacterial causative agent of the insects’ death and evaluate its utility in plant protection against pests. We estimated the 50% lethal concentration (LC50) of the microorganisms for \textit{S. exigua} larvae to confirm the pathogenicity of the bacterial strains for insects. According to the Integrated Pest Management program (Directive 2009/128/WE of the European Parliament and the Council of the European Union), application of insecticidal biopreparations should come with the lowest risk to human health (Matyjaszczyk 2018). Biological pest management can be aiming to maintain food and human safety (Mosa et al. 2016). Therefore, we decided to evaluate if the bacteria that caused the insect death are safe for humans. We examined the cytotoxic activity of the isolates to mammalian epithelial cells and the ability to produce siderophores. Moreover, the strains were verified for antimicrobial susceptibility and the presence of integrons.

**Experimental**

**Materials and Methods**

**Bacterial strains.** Eight \textit{S. marcescens} isolates (MPU S11 – MPU S18) were used in this study. They were isolated from dead caterpillars of \textit{Spodoptera exigua} cultured in the laboratory culture line in September 2009. In order to determine the clonal relationship of isolates, thirteen additional strains were included in the study as a comparative samples: \textit{S. marcescens} strain MPU S19 obtained from a dead larva of \textit{Agrotis segetum} reared in the same laboratory three months earlier, eight \textit{S. marcescens} strains (MPU S11, MPU S14, MPU S15, MPU S26, MPU S32, MPU S40, MPU S41, MPU S47) isolated from clinical specimens, one \textit{S. odorifera} (MPU Se128/7) cultured from sewage, one \textit{S. ficaria} (MPU S49), one strain of \textit{Enterobacter cloacae} (MPU E39a) from clinical specimens, and \textit{Pseudomonas aeruginosa} (MPU Pb5/4) from the intestinal tract of a wild boar.

**Bacteria isolation and identification.** Dead caterpillars were swabbed with 90% ethanol, homogenized in BHI medium (Difco) and incubated at 30°C for 24h. Then, the bacterial suspension was spread on BHI agar medium and after 24-hour incubation, the bacteria were characterized based on the morphology of colonies. Identification of bacteria was performed by API 20E tests according to the manufacturer's instruction (bioMérieux, France).

**Clonal relationship.** Bacterial typing was conducted by REP-PCR with primers REP1I and REP2I for repetitive extragenic palindromic sequences (Moura et al. 2007). One bacterial colony was suspended in 25 μl of sterile distilled water and heated at 98°C for 5 min. Two microliters of DNA were added to PCR mixture containing PCR buffer with NH4(SO4)2, 0.5 μM of each primer (Oligo.pl, Poland), 200 μM of dNTP mix, 2.5 mM of MgCl2, and 0.5 U of Allegro DNA polymerase (Novazym, Poland). PCR amplification involved an initial denaturation at 94°C for 3 min followed by 35 cycles at 94°C for 1 min, 40°C for 1 min, 72°C for 90, and a final extension at 72°C for 8 min.

Amplification products were electrophoresed in 1.5% NOVA Mini agarose gel (Novazym, Poland). The similarity of bacteria DNA profiles was estimated with Dice coefficient and a dendrogram was created by the unweighted pair group method with average linkages (UPGMA).
Pathogenicity of *S. marcescens* strains for insects.

The pathogenicity of *S. marcescens* strains against *S. exigua* caterpillars was determined. Insects originated from laboratory culture line reared at 26°C, 40–60% relative humidity, and a 16:8 (light: dark) period in the Department of Microbiology, Adam Mickiewicz University, Poznań.

The bioassay on insects was conducted according to Jeong et al. (2010), Mohan et al. (2011), and Sikorowski et al. (2001). *S. marcescens* isolates were grown in nutrient agar (Biocorp, Poland) at 30°C for 24 h. One bacterial colony was suspended in 1 ml of 0.85% NaCl. Five different volumes: 2.5 μl, 5 μl, 10 μl, 20 μl, 40 μl of the suspension were spread on pieces (5 mm diameter, 3 mm height) of semisynthetic diet for *S. exigua* rearing as described by McGuire et al. (1997). The pieces of diet were placed separately in transparent polystyrene multi-well plates. Caterpillars in L1 instar were placed onto the diet – one larva per one well with one diet piece. Each *S. marcescens* CFU number was tested against 30 larvae (three replications with 10 insects each). Simultaneously, the number of CFU per milliliter was determined by the spread plate method. The volume of 100 μl of a bacterial colony suspension in 1 ml of 0.85% NaCl. Additionally, the number of CFU per milliliter was determined by the spread plate method. The volume of 100 μl of a bacterial colony suspension in 1 ml of 0.85% NaCl, and additionally the volume of 100 μl of five dilutions of the suspension (10⁻¹, 10⁻², 10⁻³, 10⁻⁴, and 10⁻⁵) were spread on BHI agar (each dilution on two plates with medium). After the overnight incubation at 37°C, the colonies were counted and the number of CFU per milliliter was calculated. As we mentioned above different volumes of the suspension were spread on pieces (5 mm diameter, 3 mm height) of semisynthetic diet for insect rearing. The pieces had a shape of a cylinder and the formula for the surface area is πr². Knowing the value of the surface area in cm², the volume of bacterial suspension spread on the medium, and the number of CFU per milliliter, we calculated CFU/cm².

As a positive control, a strain of *Bacillus thuringiensis* subsp. *kurstaki* HD1 from biopesticide Foray was used. Foray contains bacterial endospores (spores) and protein crystals and is dedicated for plant protection against lepidopteran pests. The *B. thuringiensis* was cultured in medium developed for bacteria sporulation by Lecadet and Dedonder (1971). Spores and crystals were applied to insects in the same way as *S. marcescens*. As a negative control, 0.85% NaCl was used.

Infected insects were reared at 26°C, 40–60% relative humidity, and a 16:8 (light: dark) period. The number of dead insects was estimated after 7 days. The LC₅₀ [*S. marcescens* CFU per 1 cm² of insect diet surface] against insects was calculated by a probit analysis according to Finney, based on the mortality (%) in the control sample, by using BioStat ver. 5.8.4.3 software (AnalytSoft Inc.).

Cytotoxic activity to epithelial cells by MTT assay.

African monkey kidney (Vero) cells were cultured in Eagle Minimum Essential Medium (EMEM, Sigma) with 5% fetal calf serum (FCS, Sigma) containing 2 mM glutamine, 50 IU of penicillin per milliliter, streptomycin (100 μg/ml) and nystatin (1 μg/ml). The cells were seeded (1 × 10⁴ per well) and incubated at 37°C in an atmosphere with 5% CO₂.

The strains were cultured in Luria-Bertani medium (LB, Difco) at 37°C for 24 h with shaking at 300 rpm. The supernatants were centrifuged at 3000 × g for 30 min and sterilized through 0.22 μm-pore size membrane filters Millex-GV (Millipore) (Krzymińska et al. 2010).

The epithelial cell monolayer was incubated with bacterial culture filtrates for 24 h at 37°C. As a negative control, the cells were infected with a nonpathogenic *E. coli* K-12C600 supernatant. The cytotoxicity was assessed quantitatively by monitoring the mitochondrial reduction of 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT, Sigma) (Krzymińska et al. 2009). The data were presented as means ± standard deviation (SD) from two independent experiments performed in duplicate.

Siderophore production. *Serratia* sp. strains were verified for the production of siderophores by chrome azurol S (CAS) assay (Schwyn and Neilands 1987). The type of the siderophore excreted was identified in cross-feeding assays with the following indicators: enterobacteriaindicator – *Salmonella typhimurium* TA 2700, aerobactin and rhodotorulic acid indicator – *Escherichia coli* LG 1522, rhizoferrin and α-keto acids indicator – *Morganella morganii* SBK 3 (Reissbrodt and Rabbs 1988), and yersiniabactin indicator – *Yersinia enterocolitica* 5030 (Haag et al. 1993). Additionally, the presence of siderophore receptors for yersiniabactin, aerobactin and glycosylated enterobactin – salmochelin, encoded respectively by the *fyuA*, *iutA* and *iroN* genes, was assessed by PCR. All PCR reagents were purchased from Novazym (Poland). PCR amplification conditions and sequences of primers have been previously published (Karch et al. 1999; Johnson et al. 2000; Johnson and Stell 2000). The PCR products were separated in 1.5% agarose gel. All experiments were performed in triplicate.

Antimicrobial susceptibility. The susceptibility of the isolates to 20 antibiotics representing nine classes was determined according to the standard disk diffusion method recommended by The European Committee on Antimicrobial Susceptibility Testing (EUCAST 2014). The antimicrobials comprised: amikacin (30 μg), tobramycin (10 μg), netilmicin (10 μg), gentamicin (10 μg), ticarcillin (75 μg), ciprofloxacin (5 μg), norfloxacin (10 μg), cefotaxime (5 μg), ceftaroline (5 μg), cefazidime (10 μg), cefoperazone (10 μg), cefepime (30 μg), co-trimoxazole (25 μg), trimethoprim (5 μg), sulfamethoxazole (200 μg), piperacillin (30 μg), piperacillin/
tazobactam (30–60 μg), aztreonam (30 μg), imipenem (10 μg), and meropenem (10 μg). The production of extended spectrum β-lactamases (ESBL) was determined in the double-disc synergy test. All antibiotic discs were provided by Oxoid. Amplifications of three genes conferring resistance to sulphonamides (sul1, sul2, sul3), were conducted in a 25-μl volume with PCR buffer with NH₄(SO₄)₂, 0.5 μM of each primer (Oligo. pl), 200 μM of dNTP mix, 2.5 mM of MgCl₂, 0.5 U of DreamTaq polymerase (Thermo Scientific), and 200 ng of genomic DNA. The PCR conditions consisted of initial denaturation at 94°C, 3 min, followed by 35 cycles at 94°C for 45 s, annealing (varied; 46–60°C) for 45 s, 72°C for 90 s, with a final extension at 72°C for 7 min (Pei et al. 2006).

Presence of integrons. The integron integrase genes were detected by multiplex PCR with primers targeting three classes of the integrase genes intI1, intI2 and intI3 (Dillon et al. 2005). PCR amplifications were performed in a 25-μl volume with 2.5 μl of 10 × PCR buffer with NH₄(SO₄)₂, 0.25 μM of each primer, 100 μM of dNTP mix, 2.5 mM of MgCl₂, 1 U of DreamTaq polymerase (Thermo Scientific), and 200 ng of genomic DNA. Amplification involved an initial denaturation (94°C, 5 min) followed by 30 cycles of denaturation (94°C, 1 min), annealing (59°C, 1 min) and extension (72°C, 1 min), with a final extension step (72°C, 8 min).

Results

Bacteria identification. The strains isolated from insects were Gram-negative rods identified as Serratia marcescens with API 20E system. On the agar medium, the bacteria formed circular, raised, shiny, and smooth colonies. All isolates produced the pigment that made the colonies red.

Clonal relationship. Molecular typing revealed three groups of bacteria with 100% similarity of DNA patterns (Supplementary Fig. S1). Cluster 1 consisted of three isolates: MPU Si4, MPU Si5, and MPU Si7. Three strains MPU Si1, MPU Si2, and MPU Si3 formed cluster 2. Isolates MPU Si6 and MPU Si8 were gathered in cluster 3. These groups comprised S. marcescens isolates cultured from dead S. exigua insects. The similarity between cluster 1 and 2 was equal to 92%. Group 3 was similar to 1 and 2 in 85%. S. marcescens MPU Si9 isolated from the intestinal tract of A. segetum cultured in the same laboratory as S. exigua but in different time showed 66% similarity with S. marcescens isolates originated from S. exigua. DNA pattern of S. marcescens isolated from A. segetum was similar in 70% to the strain cultured from a clinical specimen.

Pathogenicity of S. marcescens strains for insects. S. marcescens isolates revealed insecticidal activity against S. exigua caterpillars and caused high mortality of larvae. The LC₅₀ values of S. marcescens were similar and ranged from 7.6 × 10⁸ to 5.6 × 10⁸ CFU per 1 cm² of the insect diet surface. The toxicities of S. marcescens strains were higher than the activity of spore-crystal preparation of B. thuringiensis from Foray bioinsecticide (Table I).

Cytotoxicity of S. marcescens strains. After 24 h of incubation with the strain culture supernatants, we observed cytopathic effects such as rounding and shrinking of the Vero cells. These changes were followed by the gradual destruction of the monolayer. All strains were cytotoxic to Vero cells (Table II). The highest cytotoxicity in a range from 76.6 to 79.2% was observed for five strains. Three isolates revealed cytotoxic activity, causing death from 54.9 to 59.7% of Vero cells. The supernatant of non-pathogenic control, E. coli K-12C600 did not cause the cytopathic effect.

Siderophore production. In the standard method of Schwyn and Neilands (1987), all S. marcescens strains demonstrated the production of iron chelators. Biological assays with indicator strains deficient in siderophore synthesis but capable of acquiring exogenous iron chelators indicated that all of the strains excreted catecholate siderophore – enterobactin. The PCR results showed that the strains did not have the receptor genes for yersiniabacin, aerobactin or salmochelin.

Antimicrobial susceptibility and presence of integrons. The strains were resistant toward one to three antimicrobials (Table III). All isolates were resistant to sulfamethoxazole. Moreover, they were resistant to antibiotics belonging to aminoglycosides: tobramycin (22.2%) and gentamicin (11.1%), cephalosporins: cefepime (11.1%) and monobactams: aztreonam (11.1%). We did not observe an ESBL phenotype and the integron integrases genes. Resistance to sulfamethoxazole of all strains was due to the presence of the sul1 or sul2 gene.

Discussion

In recent years some microbial insect pathogens have become useful in protecting crops against pests. Application of natural enemies of insects could be the long-term and suitable strategy. There is still a need to search for an effective and safe biopreparation against harmful crop pests, and entomopathogens of hazardous insects could be employed in the development of the biopreparations (Bahar and Demirbağ 2007; Nuñez-Valdez et al. 2008). S. marcescens strains are proposed to be used as biocontrol agents because of their insecticidal activity against lepidopteran larvae (Sikrowski et al. 2001; Jeong et al. 2010; Mohan et al. 2011) of all developmental stages (Aggarwal et al. 2015). However, the proposal mentioned above ignored the issue of bacterial safety for humans and other non-target vertebrates. We observed the death of insect caterpillars of S. exigua and A. segetum in the laboratory culture lines. We isolated and identified the bacterial causative agent of dead insect and determined the pathogenic properties of insecticidal S. marcescens strains to humans.

For determining the possible clonality of strains, we applied the REP-PCR typing method to determine the genetic similarity of Gram-negative rods (Rasschaert et al. 2005; Henriques et al. 2006; Moura et al. 2007; Czajkowski et al. 2010; Mokracka et al. 2011). The analysis revealed a high similarity of all S. marcescens isolates cultured from S. exigua intestinal track. DNA profiles of strains that caused infections of S. exigua varied significantly from that of the strain infecting A. segetum. The strains made three clusters, yet we did not treat them as clones as they differed in resistance profiles and cytotoxic activity.

We confirmed entomopathogenicity of S. marcescens isolates. The insecticidal activity of strains indicates the usefulness of the bacteria in plant protection. The low values of LC50 of S. marcescens against caterpillars in comparison with LC50 of spore-crystal preparation of B. thuringiensis from Foray suggested the possibility to create a novel biopesticide based on S. marcescens with high activity against lepidopteran pests. However, the preparation could not have harmful effect for non-target organisms, so we examined the cytotoxic activity of the isolates to mammalian epithelial cells, determined the siderophore production, antimicrobial susceptibility, and the presence of integrons in S. marcescens genomes.

We observed that culture filtrates of S. marcescens strains isolated from insects were capable of damaging mammalian epithelial cell line. Escobar et al. (2001) have reported that supernatants of S. marcescens isolates from plants and insects were cytotoxic to epithelial cell lines. Strains originated from the stomach of Rhodnius prolixus larvae revealed hemolytic activity (Azambuja et al. 2004). Toxin production by entomopathogenic strains is still not clearly defined. Hertle (2005) has suggested that hemolysin produced by S. marcescens strains (ShLα) is the major cytolysin in the pathogenesis of the bacteria. The toxin induces the formation of pores in erythrocytes and eukaryotic nucleated cells, which results in osmotic lysis. Moreover, the bacteria produce extracellular lecithinase, proteinase, and chitinase that play a role in their virulence for insects (Grimont and Grimont 2006). Similar cytotoxic destruction of epithelial cells has been observed for strains isolated from human specimens (Krzymińska et al. 2010). The results presented in this study suggested that extracellular factors produced by the isolates could be responsible for the destruction of the epithelial barrier, which could pose a potential risk to human health.

Iron sequestration involving siderophores is a recognized factor essential for bacterial pathogenicity. Deletion of siderophore biosynthetic genes leads to loss of pathogenicity in a mouse infection model, and also affects maturation of biofilms, surface motility, activation of exotoxins and synthesis of other virulence factors (Vokes et al. 1999; Visca et al. 2007; Mossialos and Amoutzias 2009). Enterobactin, which is a prototypical catecholate siderophore with the highest known affinity for iron, was excreted by all S. marcescens strains (Supplementary Table SI). Its role in pathogenesis is limited, as in host it is bound by siderocalin (lipocalin 2, Lcn2)

*ATM – aztreonam, GEN – gentamicin, SUL – sulfamethoxazole, TOB – tobramycin

Table III
Antibiotic resistance of S. marcescens strains isolated from insects.
that inhibits bacterial iron acquisition (Flo et al. 2004). Other siderophores like structurally distinct yersiniabactin or salmochelin, which is glycosylated enterobactin, deliver iron to bacteria despite the presence of Lcn2, yet we did not find receptors for these chelators.

We did not find integrons in the genomes in S. marcescens strains although all of them were resistant to sulfamethoxazole, suggesting the presence of class 1 integrons, which have the sul1 gene at the 3' integron end. The resistance to sulfamethoxazole was determined by the sul1 or sul2 genes that code for dihydropteroate synthases, which are not inhibited by sulfonamides (Pei et al. 2006). The resistance of single strains to aztreonam and cefepime may be the result of overproduction of β-lactamase and resistance to amino glycosides, which is often noted in clinical strains of S. marcescens. It is most frequently determined by the presence of the plasmid-mediated aminoglycoside-modifying enzymes. Both the sul genes and those conferring resistance to β-lactams and aminoglycosides may reside on mobile genomic elements and be spread via horizontal gene transfer (Stokes and Gillings 2011).

Our research confirmed the potential pathogenicity to humans of S. marcescens strains lethal for insect pests. We decided to undertake this issue because S. marcescens is proposed to be a useful bioinsecticide (Sikorowski et al. 2006). We decided to undertake this issue because S. marcescens is proposed to be a useful bioinsecticide (Sikorowski et al. 2006). Jeong et al. 2010; Mohan et al. 2011; Aggarwal et al. 2015); however, the pesticidal biopreparations cannot be harmful to non-target organisms. The ability of S. marcescens to damage mammalian epithelial cell line and to employ siderophore-mediated strategies of iron acquisition eliminates the bacterial cells to be used as a bioinsecticide. Using the antimicrobial resistant, potentially pathogenic to humans S. marcescens strains in plant protection may cause human infections difficult to cure and lead to the spread of resistance genes. We emphasize the necessity of determining the safety to vertebrates of the bacteria that are proposed to be used as a biocontrol preparation for reducing the number of insects. Yet, it is worth mentioning that bacterial strains harmful for pests could be a source of novel genes or factors useful in controlling insect pests. In our further studies, the insecticidal factors-coding genes in S. marcescens strains will be identified, cloned and expressed in E. coli cells (Baranek et al. 2015). After isolation and purification of the genes' products, their insecticidal activity against lepidopteran pests will be determined.
